Carbon molecules: Introducing our new analytical workflow

*ETC Commissioners Meetings
31st October 2024*

Objectives for the session

1

Introduce the **ETC carbon molecules project** (supported by QCF) **project objectives** and **deliverables**

2

Test **hypotheses** on the “**unconstrained electrification/ hydrogen scenario**” accelerated by **technology disruptions**

3

Share **next steps** and **opportunities** of offering **inputs**

Agenda

Project overview

Previous projections on electrification and hydrogen

Trends and tech disruptions shaping ETC scenarios

Sectoral deep-dives

Carbon molecules

Project - Carbon molecules within a low emissions energy system

Aim

Global assessment of demand and sustainable, feasible supply of molecules

Carbon molecules in the zero-emission economy: proposed work programme

1. How large a role can and should direct electrification play in a zero-emission economy?

- Develop an **extreme scenario** which identifies how much of the economy could **in principle be electrified** if zero carbon electricity were available at a very low cost and on the required scale
- A revised version of our **Possible but Stretching scenario** which describes the optimal role of electricity

2. The role of hydrogen and non-carbon H₂ derivatives

- Develop an **updated set of scenarios for the role of hydrogen**, exploring in particular the balance between hydrogen and non-carbon H₂ derivatives relative to carbon and hydrocarbon molecules in different sectors

3. The potential to recycle and reuse carbon molecules

- Developing another **extreme scenario to explore how close to total recycling** of all carbon molecules it would be possible to get, and with what implications for the primary supply of new carbon still required to support a prosperous global economy
- Produce **a range of less extreme plausible scenarios** for carbon source demands in a zero-emission economy

4. Sources of primary carbon: costs and sustainability

- Assess whether there is a case for **increasing or decreasing our past estimates** of potentially sustainable bioresource supply
- Review the latest **technology development** and **cost trends** in point source capture and direct air capture of CO₂ (DACCS)
- **Engage with Brazil's distinctive viewpoint** by establishing an ETI Brazil effort to assess the optimal decarbonisation path within Brazil's specific conditions

Molecules will likely be essential in aviation, chemicals, fertilisers, shipping; for other sectors electrification will likely dominate

Likelihood of role	Potential Application	Current Fossil Fuel Demand ¹			Sector power demand in 2050 Final and Intermediate	Share of electricity in FED in 2050
		Coal	Gas	Oil		
Most likely role for molecules	Aviation			5.5 mb/d	5,000 TWh	
	Shipping			5 mb/d	1,000 TWh	
Some role, depending on costs vs. electrification	Plastics and Petrochemicals			17 mb/d	2-10,000 TWh	
	Fertilisers/Ammonia	230 Mtce	500 bcm			
	Iron / Steel-making	900 Mtce	100 bcm			
Minimal role – electrification wins	Other industry	750 Mtce	600 bcm	4 mb/d	7,000 TWh	
	Power, Road Transport, Buildings	4,000 Mtce	3,000 bcm	67 mb/d	35-40,000 TWh	

¹ Demand is for direct use of fossil fuels.
Source: Systemiq analysis for the ETC; ETC (2023), *Fossil Fuels in Transition*.

What kind of molecules, from where, is still an open question

Likelihood of role	Potential Application	Options for low-carbon molecules
<p>Most likely role for molecules</p>	<p>Aviation</p> 	<ul style="list-style-type: none"> • Biofuels (HEFA-based or other e.g., from gasification) • Synthetic fuels enabled by carbon streams (likely from point-source or direct-air capture) and low-carbon hydrogen • Potential for continued use of fossil-based jet fuel together with carbon removals
	<p>Shipping</p> 	<ul style="list-style-type: none"> • Low-carbon hydrogen to make ammonia • Methanol – requires both low-carbon hydrogen and additional carbon atoms
<p>Some role, depending on costs vs. electrification</p>	<p>Plastics and Petrochemicals Fertilisers/Ammonia</p> 	<ul style="list-style-type: none"> • Low-carbon hydrogen in combination with... • ... carbon atoms from multiple potential sources: bio-based and recycled feedstocks, from fossil fuels, or captured carbon
	<p>Iron -making</p> 	<ul style="list-style-type: none"> • Low-carbon hydrogen for use in direct reduction of iron • ... but also multiple options for recycling of carbon and hydrogen rich off-gases • ...and carbon capture may make iron making a source of carbon for other sectors
	<p>Other industry</p> 	<ul style="list-style-type: none"> • Some role for bioenergy or hydrogen in combustion for provision of mid/high-temperature heat
<p>Minimal role – electrification wins</p>	<p>Power, Road Transport, Buildings</p> 	<ul style="list-style-type: none"> • Small role for molecules in: <ul style="list-style-type: none"> - Storage (low-carbon hydrogen) - Balancing (low-carbon hydrogen or bioenergy) - Heavy-duty trucking (low-carbon hydrogen >> bioenergy)

Source: Systemiq analysis for the ETC; ETC (2023), *Fossil Fuels in Transition*.

Previous ETC reports have assessed the relative role of role of CCUS, bioresources and hydrogen

- CCUS is vital but limited:
 - Where **alternatives are technically limited** (e.g., Cement process emissions)
 - To provide **least-cost decarbonisation** in key sectors and geographies where CCUS is competitive
 - To provide some **carbon removals**
- Enabling **transport & storage infrastructure** will be crucial – CCUS clusters could be important
- Most recent ETC analysis estimates **7-9 GtCO₂ of CCUS**, of which 4-5 GtCO₂ is point-source applied to fossil fuels and 3-4GT CO₂ is DAC

- Use of Bioresources faces **strong land use competition** and **sustainability constraints**
- A “prudent” estimate of sustainable biomass supply would be **40-60 EJ in 2050** – could rise up to 120 EJ in a “max. potential” scenario
 - Producing 50 EJ/yr could need **~2.8 million km² of land** (~8% of agr. land)
- Use of biomass should be **prioritized for sectors where alternatives are limited:**
 - Pulp and paper, timber
 - Plastic feedstocks
 - Aviation
 - Some high/mid-temperature heat

- **Green hydrogen** could be competitive with grey by 2030s (though latest progress slow)
- **Blue hydrogen** will also have a role – competitiveness depends strongly on cost of gas and availability of CCS
- Priority should be to **displace existing ~95 Mth₂ of grey hydrogen demand first**, then expand into wider sectors
- Enabling **transport & storage infrastructure** will be crucial
- Most recent ETC analysis estimates **350-600 Mth₂ of demand in 2050**, with greatest role in chemicals, steel, aviation and shipping

Source: ETC (2021), *Bioresources within a net-zero emissions economy*; ETC (2021), *Making the hydrogen economy possible*; ETC (2022), *Carbon capture, utilisation and storage in the energy transition*; ETC (2023), *Fossil fuels in transition*.

Phase 3 and 4 will get to the heart of the molecules question

The potential to recycle and reuse carbon molecules

Assessment of:

- Combined energy and materials system demand for carbon molecules
- Linear vs. circular systems
- Novel recycling processes – including mechanical recycling, depolymerization, gasification & pyrolysis
- Relative energy requirements, costs and emissions implications.

Output: high and low recycling scenarios to understand volume of low-carbon molecules that may be required.

Sources of primary carbon: costs and sustainability

Assessment of:

- Latest technological developments and cost trends in point source carbon capture (CCS) in different applications.
- Latest technological developments and potential future costs trends in direct air capture of CO₂ (DACCC).
- Potential to extract and use bioresources in a cost effective and truly sustainable way, considering sustainability parameters like: full life-cycle carbon emissions, local biodiversity impacts, competition with other uses of land including food production and local community impacts.

Output: revised vision of low-carbon molecule use in a net zero energy system.

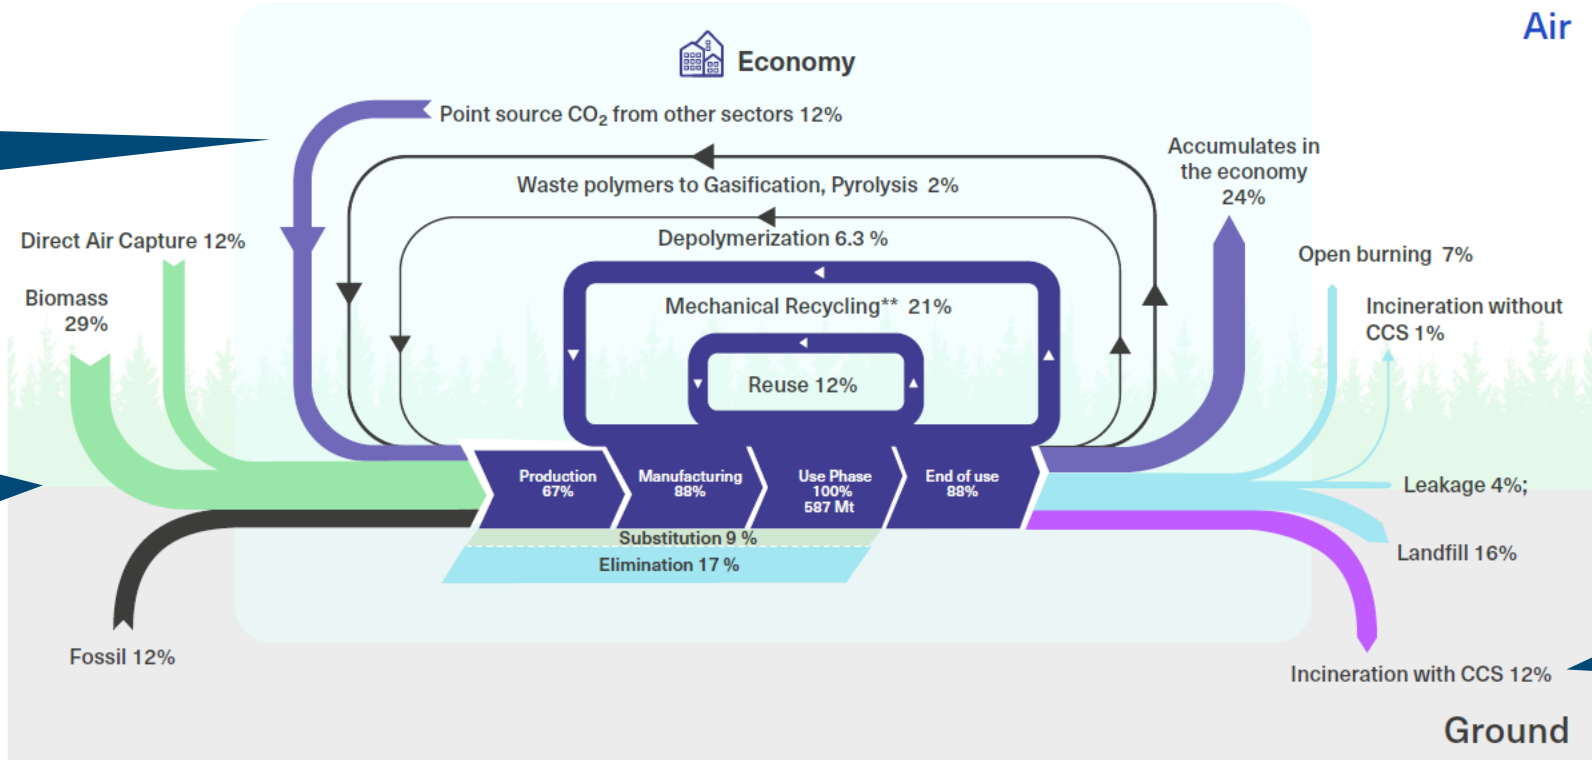

Carbon capture offers an opportunity to “recycle” carbon atoms

Figure 22: Flow of chemical industry carbon from feedstock to end-of-life – LC-NFAX Scenario 2050

Increasingly, sourcing carbon feedstocks from the atmosphere can charge the chemicals system and has potential for generating negative emissions

2050 Low Circularity – NFAX Scenario

Multiple avenues for recycling of carbon-intensive molecules

Range of potential input sources for carbon atoms

Utilisation of captured carbon from incineration could be another input stream

Note: Substitution and Elimination represent the % chemicals that will be reduced through LC levers.
^{*}Point Source - Incineration + CCU assumes all chemical related energy recovery emissions are circulated back
^{**}Mechanical recycling includes solvent-based recycling technologies over a long term time horizon chemicals stored in the economy (e.g. construction plastics averaging 35 year life spans) will begin to churn out. All circulated carbon in Mt and as % of total use phase utility (i.e. including sub and elimination).

Innovation could free up land, increase the potential for recycling and reduce the energy inputs needed for molecular transformations

Synthetic biology / precision fermentation > synthetic meat

- Huge theoretical potential to reduce food land use, given inherent inefficiency of both photosynthesis and cattle-based conversion of vegetable to meat protein
- Challenges of cost-competitiveness and consumer acceptance

Bioreactors/ microbial biocatalysts (e.g. Lanzatech)

- Reducing energy demands for multiple variants of molecular transformation
- Enabling lower cost conversion of waste, residues and CO₂ streams into ethanol, other fuels, chemicals

Chemical recycling

- Depolymerization (via e.g. catalytic cracking – breaking down long hydrocarbons)
- Feedstock recycling (via e.g. pyrolysis or gasification)
- New catalysts significantly reducing required energy inputs

Electrochemical technologies

- e.g CO₂ electrolysis (“Twelve”) reducing cost of CO₂+H₂ synthesis into jetfuel

How fast can these technologies develop and cost-reduce?

What implications for balance between:

- Continued fossil fuel use + CCS
- Sustainable bioenergy supply and bioenergy applications
- Continuous recycling of carbon atoms

Today we focus on sprint 1: evaluating the role of direct electrification, hydrogen and its derivatives in achieve a zero-emission economy

Agenda

Project overview

Previous projections on electrification and hydrogen

Trends and tech disruptions shaping ETC scenarios

Sectoral deep-dives

The ETC updated its total final energy demand view in the Fossil Fuel phase down report published last year

Electricity will need to go from 20% → 55-70% by 2050

Final Energy Consumption, EJ

Role of Molecules:

- **30-45% of overall Final Energy Demand**, of which:
 - 10-15% is **hydrogen or derivatives**
 - 5-10% is **biomass-derived carbon**
 - 10-25% is **fossil carbon**

Areas where ETC will refine:

- Volume of hydrogen demanded, particularly in the chemicals sector
- Indirect power consumption from hydrogen consumption, accounting for blue/green split
- 'Other industry' energy demand

Note: ACF = Accelerated but Clearly Feasible; PBS = Possible but Stretching. Wood products and pulp and paper excluded from modern biomass
Source: ETC (2023), *Fossil fuels in transition*.

Mission Possible 2018: the ETC's first attempt at a final energy mix in a zero-carbon economy

Note: Steel energy mix represents the supply-side pathway only. For chemical feedstock, inputs are not used as energy but in order to provide the molecules required to build the chemicals. In our model, for comparison we express it in EJ equivalent.

Most recent forecasts on hydrogen are revising down its role in the decarbonization journey

Global hydrogen demand has been revised downwards, Mt H2

■ Previous projections ■ Updated projections

Source: IEA (2023), World Energy Outlook 2023; IEA (2021), World Energy Outlook 2021; Hydrogen insights (2024), 'Getting to net zero will need nearly a quarter less clean hydrogen than we initially predicted'; BNEF; Hydrogen insights (2023), Half of all clean hydrogen produced globally could be transported long-distance by 2030, says Hydrogen Council. ETC (2021), Making the Hydrogen Economy Possible. ETC (2023), Fossil Fuels in Transition

Incremental trends and disruptive innovations require analysis to understand how far electrification and hydrogen can go towards decarbonization

Returning to ETC's view will involve taking stock of

- 1. Incremental Changes** – reviewing latest trends and what has changed particularly in usage and cost of renewables, batteries, new energy demand (e.g. data centres), CCS and biofuels
- 2. Disruptive/innovative technologies** – new technologies, such as Molten Oxide Electrolysis for steel making or electric steam crackers for the chemical industry. What does it take to believe that these disruptions will materialize?

The new ETC constrained and unconstrained scenarios will highlight the potential range of electrification by 2050

Agenda

Project overview

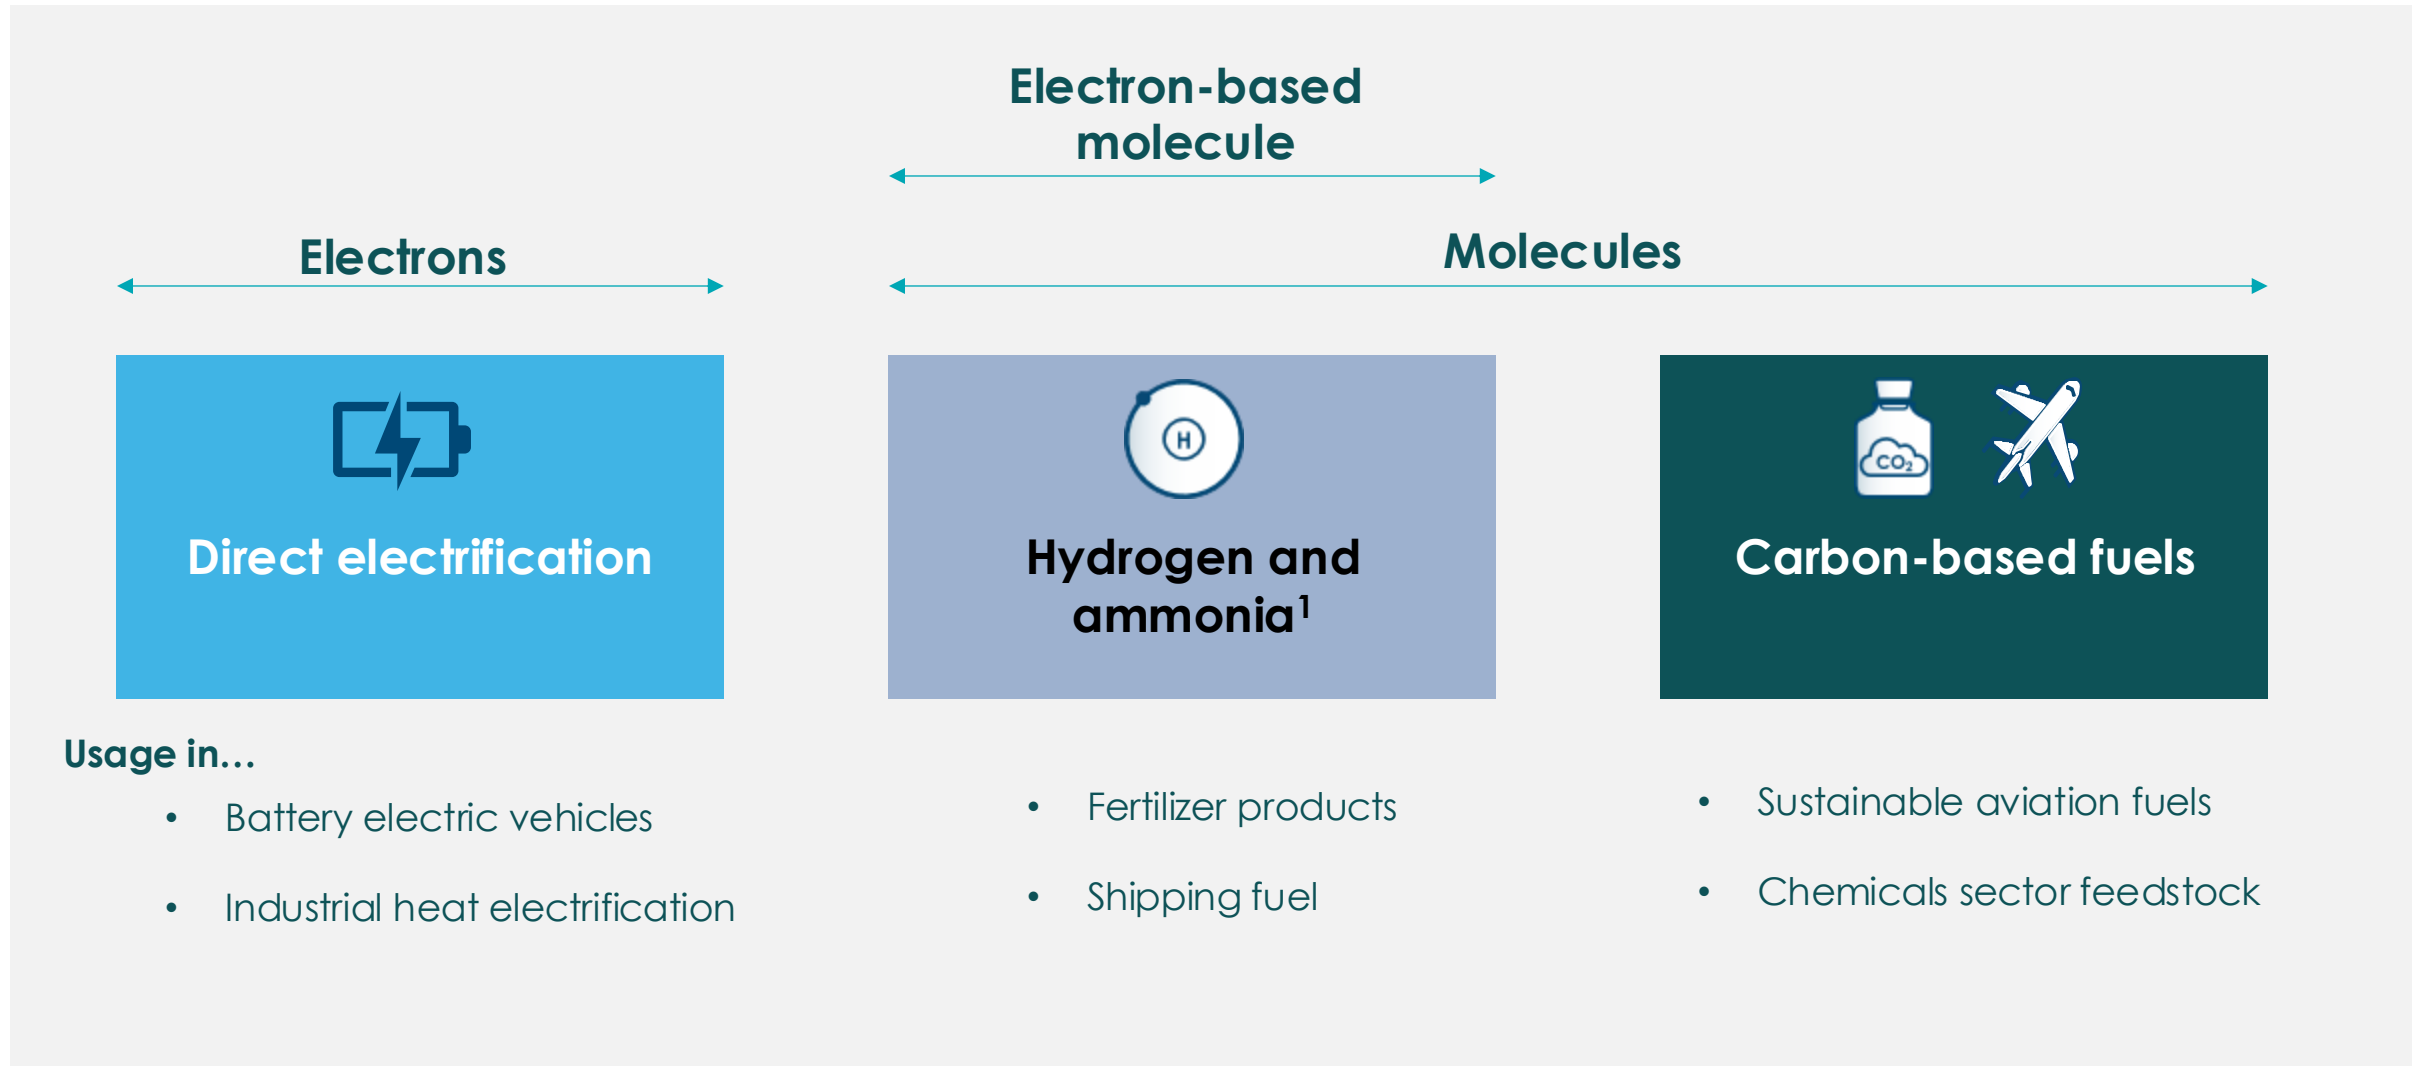

Previous projections on electrification and hydrogen

Trends and tech disruptions shaping ETC scenarios

Sectoral deep-dives

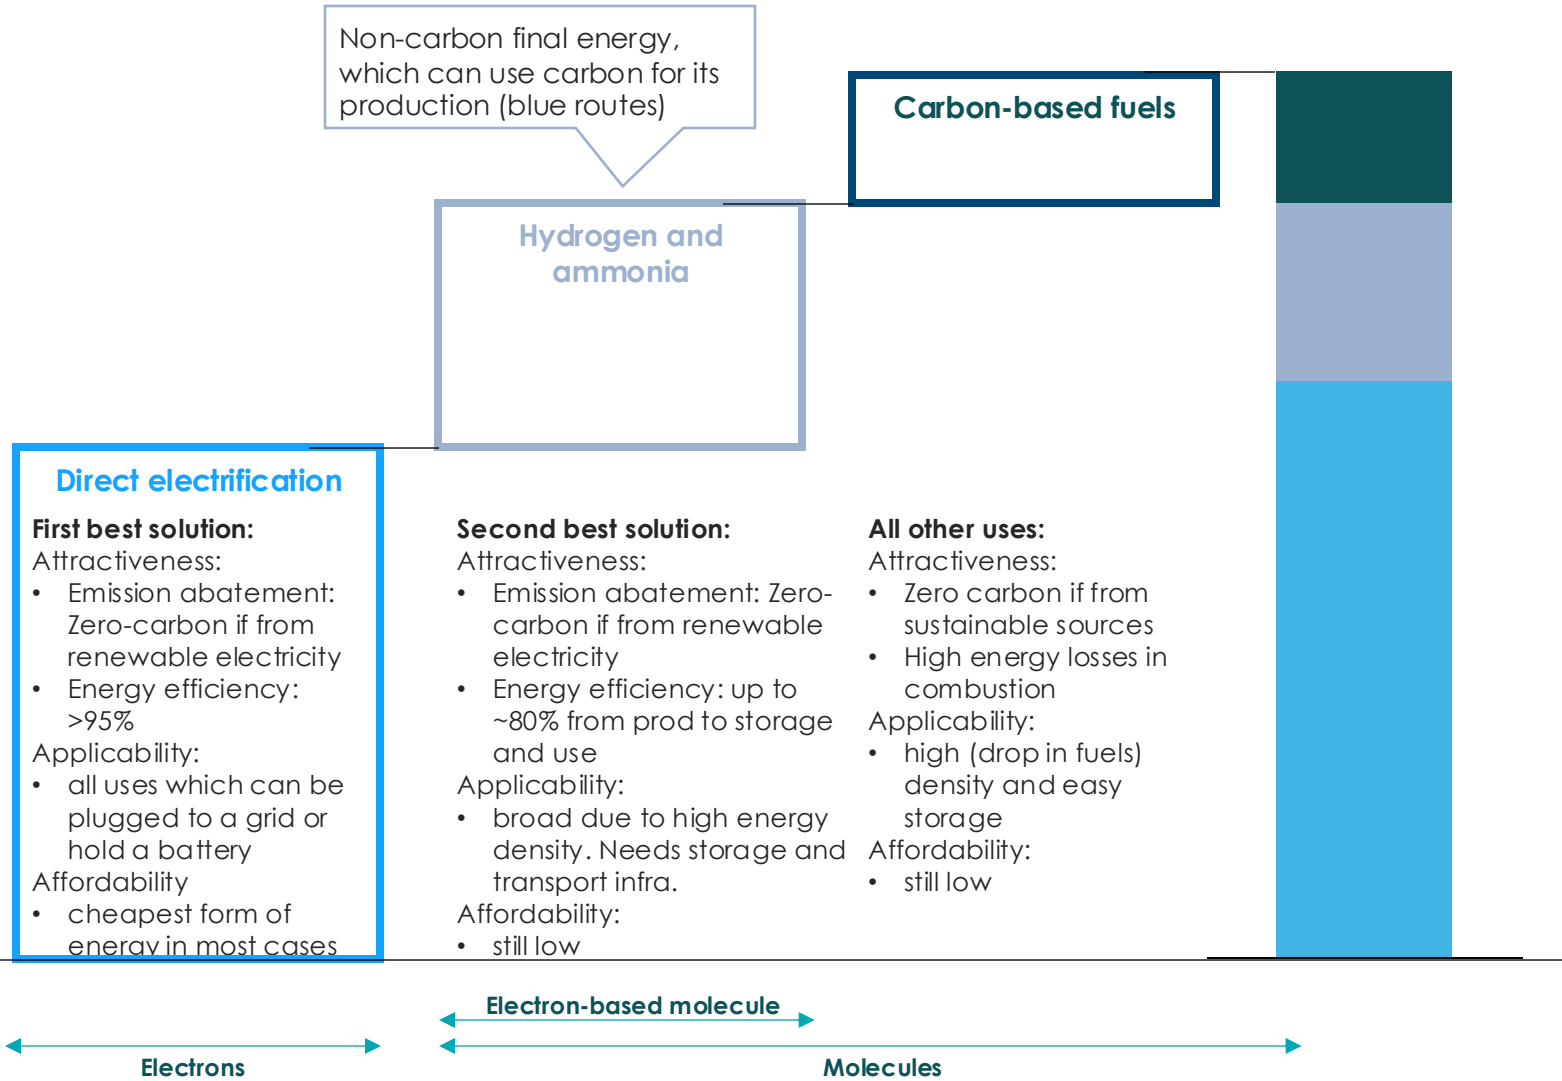

Three main energy sources in a net-zero economy

Notes: 1) Non carbon energy carriers, potentially produced using carbon (blue routes)

The three main energy uses in a net-zero economy are clear – uncertainty lies in their relative sizes

Focus of the next sprint

- How much carbon do we need in a net zero economy?
- How much can be sourced by recycling and reuse?
- How much remaining carbon must be sourced by non-fossil carbon sources?

Focus of this sprint

- How much can electrification and hydrogen cover in term of uses?

Estimated in ETC's FFIT report¹

- How much energy demand do we need in a net-zero economy?

Notes: 1) FFIT = Fossil Fuels in Transition Report, ETC (2023)

New observed trends show the necessity to update and question the relative importance of direct electrification, hydrogen and carbon-based fuels

Trends related to

Direct electrification: ACCELERATING

Non carbon use of hydrogen: STAGNATING

Carbon-based fuels: PLANETARY BOUNDARIES & LOCK-IN TRENDS

TREND PROOFPOINT

1 [Cost] Solar PV costs decreasing faster than anticipated 75% reduction in average estimated Solar PV LCOE and 75% reduction of panel cost in the past 10 years

2 [Cost] Battery costs decreasing faster than anticipated 85% cost reduction over the last decade

3 [Use] Expanding energy uses add extra power demand short term energy demand from AI and AC (IEA 2024)

TREND PROOFPOINT

4 [Cost] Much lower price decline due to inflation and system costs BNEF electrolyzer cost estimate increasing 90% between 2022 & 2024

5 [Use] Scale up of green hydrogen production stagnating Only 4Mt of 118Mt H₂ production in pipeline at FID/operational

6 [Use] Use cases are increasingly shifting from H₂ to electrification Abandon of H₂ for buildings and trucking projects

TREND PROOFPOINT

7 [Cost] Biofuels and CCS prices expected to remain relatively flat Medium to long term projections from MPP, BNEF and OECD

8 [Use] Methane leakage issue not solved Large methane emission events rose by 50% in 2023 compared with 2022

9 [Use] Increased use of gas and oil in chemicals feedstock Chemical industry growing, with over 55% of oil and gas still being used for process energy

[Power] The decline in solar PV costs has been underestimated in the past and is project to reduce further

Cost of solar PV in IEA progressive scenarios, USD/kW, real capital cost from year of report

BNEF projected LCOE of Solar PV¹ globally & select countries USD/MW (2022 real)

IEA scenarios in World Energy Outlook reports

[Batteries] costs have increased in 2022 but have gone due to innovations in applicable minerals to use and reduction of EV demand

Full system cost of two-hour energy storage
USD/kWh

Chinese battery costs, Jan 2023 – Feb 2024
USD/kWh

Key trends

- **Battery rack prices surged** in 2022-2023 due to rising demand for EVs and shortages of critical materials like cobalt and nickel.
- **Battery costs declined in 2023** as LFP batteries, which do not rely on nickel or cobalt, gained market share, offering a cost-effective alternative.
- **LFP batteries dominate energy storage**, making up 80% of new storage installations in 2023, thanks to their lower cost and longer lifespan, while nickel-rich chemistries remain crucial for EVs due to their higher energy density.

Notes: LFP = Lithium iron phosphate battery, Battery racks contain multiple battery packs or modules arranged to provide higher capacity
Source: BNEF; IH 2024 Energy Storage Market Outlook, IEA (2024) Global EV Outlook

[Hydrogen] Electrolysis system costs are higher than initially expected; reflecting better understanding of full system complexity

Previous understanding of the costs

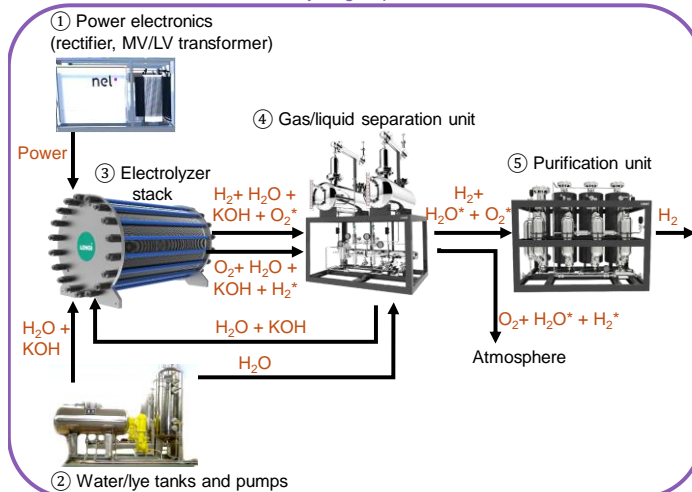

Current understanding of the costs

Installed costs

Direct costs

Hydrogen production

Installed costs

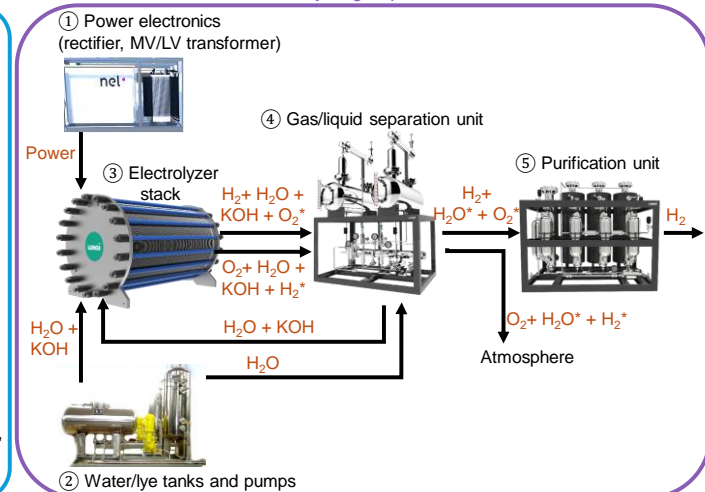

Direct costs

Hydrogen production

Further process

Utilities

- Power (HV transformers, switch gears, long-distance cables)
- DM water generation (raw water purification, water desalination, connection to a remote water source, water buffer tanks)
- Cooling (chiller, cooling water tower)
- Nitrogen supply (to render the system inert and create a safe environment upon startup and following electrolyzer system maintenance)
- Other ancillary service (fire fighting, lightning protection, lighting, central control, telecommunication, etc.)

- Temporary hydrogen storage
- Hydrogen compression (up to 40 bar)

Indirect costs

- EPC management (EPC contractor selection and management)
- Owner's costs (land and grid fee, insurance, permitting, financial arrangement, feasibility study, pilot tests/ramp up costs, etc.)
- Contingency (budget put aside to cover any unforeseen costs, risks and events)

[Hydrogen] Costs of hydrogen remain high, and anticipated to fall less steeply than anticipated in light of higher system capex

System capex forecast of large alkaline electrolysis projects
\$/kW

BNEF electrolyzer survey reports

Electrolyzer system costs
\$ per kw of hourly hydrogen yield

Note: Years refer to time of final investment decision (FID), engineering, procurement and construction bidding closure or equipment purchase. There was no trade barrier in 2023, so the 'premium due to trade barriers' was not available then. The unit '0.2Nm³/h' is equivalent to kw under the current industry consensus

The cost of high temperature heat electrified solutions are competitive with more carbon intensive alternatives

Levelised Cost of Heat (LCOH) for temperatures >100 degrees Celsius
\$/MWh

Notes: LCOH reflects US prices; Natural gas LCOH is based on 2024 LNG price of \$40/MWh
Source: Rondo (2024) *Can a brick solve your heat challenge?*

No significant economy of scale or learning curve effect for biofuels and CCS, which costs are expected to remain flat in the next decade

Biofuel prices,
USD/HJ (Real price)

Key trends

- Gradual decrease of ethanol and biodiesel over the next decade
- Stagnating demand growth due to diminished demand for transport fuel, with the prevalence of EV

Cost of Carbon capture and Storage, Point Source
USD/t CO₂

Key trends

- No clear cost reduction for CCS expected, but significant cost decreases possible with modular capture units
- The lack of transport and storage capacity is going to be a major bottleneck for deployment

Sources: Mission Possible Partnership (2022) Internal analysis; BloombergNEF 2023) Carbon Capture Cost Model. OECD (2024) OECD-FAO Agricultural Outlook 2024-2033; ETC (2022) Carbon Capture, Utilisation & Storage in the Energy Transition: Vital but limited

Innovation is crucial: eight pivotal disruptions may change the electrification vs. hydrogen vs. carbon boundary

				■ Electrification ■ Nuclear ■ Hydrogen	
		Technology disruption	Assessment of disruption	Sectors impacted	Certainty ¹
Cross sectoral	1	Sodium-based battery technologies	Enable low-cost, long-duration storage, challenging hydrogen and nuclear	<div style="display: flex; flex-wrap: wrap;"> <div style="width: 50%;"> Power</div> <div style="width: 50%;"> Industry</div> <div style="width: 50%;"> Mobility</div> <div style="width: 50%;"> Buildings</div> </div>	High
	2	Advanced Direct Air Capture (DAC)	Boosts e-fuels (synfuels) efficiency and lowers costs, outcompeting biofuels	<div style="display: flex; flex-wrap: wrap;"> <div style="width: 50%;"> Industry</div> <div style="width: 50%;"> Chemicals</div> <div style="width: 50%;"> Aviation</div> <div style="width: 50%;"> Power</div> </div>	Medium
	3	Nuclear micro reactor and/or fusion	Provide ultra-cheap round-the-clock power generation	Chemicals	Low
	4	White hydrogen AND/OR Advanced electrolyser efficiency	Drives (green) hydrogen to cost parity with carbon fuels and CCS	<div style="display: flex; flex-wrap: wrap;"> <div style="width: 50%;"> Power</div> <div style="width: 50%;"> Chemicals</div> <div style="width: 100%;"> (Heavy-) industry</div> </div>	Low
Sector specific	5	Li-ion solid state batteries	Outperforming other batteries in compactness, weight and charging speed	<div style="display: flex; flex-wrap: wrap;"> <div style="width: 50%;"> Trucking</div> <div style="width: 50%;"> Shipping</div> <div style="width: 50%;"> Aviation</div> <div style="width: 50%;"> Power</div> </div>	High
	6	Molten Oxide Electrolysis	Enables fully electric primary steel production	Steel	Medium
	7	Electrical steam cracking	Replace fossil-fuel cracking by electric cracking for ethylene and propylene	Chemicals	Medium
	8	Industrial heat electrification (>600°C)	Make electrification feasible and cost-competitive with CCS until high temperatures	(Heavy-) industry (cement)	High

1) Indicates the expected level of certainty that this technology will disrupt the described sectors and change share of electrification by 2050.

The eight key disruptions are shaping our unconstrained scenario

→ ↗ ↓ ↑
Changes in energy demand

		Electrification	Nuclear	Hydrogen	Impact on energy demand and size of the impact in 2050		
Technology disruption		Impact assessment (What changes, by how much?)			Direct elec	H2 + derivatives	Carbon-based
Cross sectoral	1 Sodium-based battery technologies	Enabling >90% of zero-carbon power supply with low-cost, long-duration storage			↑ + X EJ	↗ - Y EJ	↓ - Y EJ
	2 Advanced Direct Air Capture (DAC)	Increase synfuels share to [60%] v biofuels for aviation			↘ + X EJ	↑ - Y EJ	↗ - Y EJ<
	3 Nuclear micro reactor and/or fusion	Enabling >90% of renewable power supply			↑ + X EJ	↗ - Y EJ	↓ - Y EJ
	4 White hydrogen AND/OR Advanced electrolyser efficiency	H2-based fuels and tech will be cheaper, faster			↓ + X EJ	↑ - Y EJ	↓ - Y EJ
Sector specific	5 Li-ion solid state batteries	Enabling higher shares of electrification in long-haul transport			↑ + X EJ	↗ - Y EJ	↓ - Y EJ
	6 Molten Oxide Electrolysis	[100%] electrified steel production			↑ + X EJ	↗ - Y EJ	↓ - Y EJ
	7 Electrical steam cracking	[X%] electrified chemicals production instead of CCS			↑ + X EJ	→ - Y EJ	↓ - Y EJ
	8 Industrial heat electrification	Electrified low-med. °C increasing share of direct elec. to [>80%]			↑ + X EJ	→ - Y EJ	↓ - Y EJ

1) Indicates the expected level of certainty that this technology will disrupt the described sectors and change share of electrification by 2050.

Example - A disruption of electric kilns could replace fossil fuels, raising electricity needs from 12EJ to 19 EJ

Description: Electric kilns can reach 1400°C, converting limestone into clinker, the main ingredient for cement production. Switching to electric kilns can cut energy emissions, which contribute to 45% of total cement production emissions.

What we need to believe in

	Today	2050
TLR	5-6	9 (in 2040)

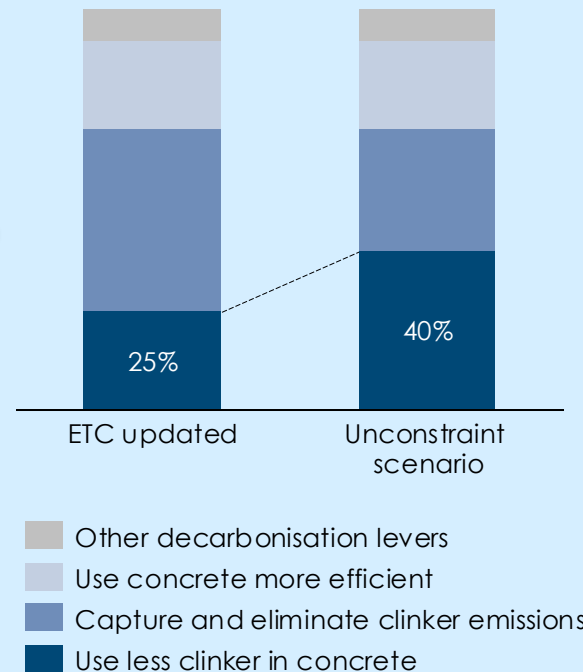

Energy cost to be competitive (EUR/MWh)	[50]	[35]
---	------	------

- Barriers mitigated**
- High temperature requirements
 - Pilot testing and scaling up
 - Reducing upfront high capital cost

- Latest developments**
- In 2023, **COOLBROOK®** successfully completed test of 1000 C
 - **SaltX** working on an electric arc calciner
 - Several MoU with steel and cement producers (**CEMEX**, **UltraTech**, **Dalmia Cement**) to electrify the manufacturing process

Abatement levers in the unconstrained scenario, % of cumulative abated emissions

Illustrative

Impact on energy demand, EJ per year

Preliminary

Agenda

Project overview

Previous projections on electrification and hydrogen

Trends and tech disruptions shaping ETC scenarios

Sectoral deep-dives

Ingoing hypothesis about dominant solutions, potential barriers and breakthroughs will help inform scenarios

No doubt electrification sectors

Passenger cars: Cost parity with fossil vehicles already possible

Short to mid-haul trucking: Cost parity projected to be reached in 2030's

Secondary steel production: already electrified

Rail: already mostly electrified

Aluminium: already electrified

Fading barriers

Long distance trucking: lowering power and battery costs makes full electrification achievable in nearly all use cases

Other industry: lowering power cost and new tech allows cost-competitive electrification to reach >600°C

Buildings: tolerance towards NG fading, leaving room for multiple electrification technologies

Long haul aviation: Lowering power and DAC costs make synfuels competitive with biofuels

Shipping: Lowering power costs make ammonia competitive with biofuels

Potential breakthrough

Power sector: nuclear and sodium batteries

Primary steel: Molten Oxide Electrolysis enables fully electric primary steel production

Short haul aviation: Battery technology and cheap renewables enabling more adoption of short-mid range H2 and battery electric aircraft

Cement: electric kilns uptake (high temperature industrial heat electrification)

Chemicals: new and efficient hydrogen production, e.g. white hydrogen, SOEC. Also electric steam crackers and methane pyrolysis

Appendix

Hypothesis for Phase 1 – how far can electrification take us?

Exam questions:

- How large can and should the role of direct electrification be in a zero-emission economy?
- What is the role of hydrogen and derivatives (i.e., ammonia) in a zero-emission economy?

Summary

1. Intro: “When facts change, I change my mind”. The ETC has previously undertaken analysis, estimating the required final energy demand mix to 2050 required for net-zero alignment.
 - a) However, informed observers and experts have consistently updated upwards their electrification deployment forecasts
 - b) Trends around deployment of renewable energy have continually been revised up, while some recent forecasts of hydrogen's role have been revised down
 - c) To understand the role of carbon molecules, in light of evolving incremental trends and incumbent technology disruptions, it is necessary to revise the ETC's view on the energy mix required
2. The role of direct electrification, electron based molecules (ammonia and H₂) and carbon based fuels is clear in decarbonization of the energy system, but less certain is how much is required of each
 - a) In view of capacity and cost trends in these three areas by 2050, we expect future energy demand to be even more electrified than we thought
 - b) Trends and short-term foreseeable development should be considered such as: higher deployment of RE, more conservative cost reductions in H₂, reducing costs of batteries, cost competitive solutions for electrifying industrial heat, and biofuels and CCUS cost projections flatlining
 - c) From a longer-term POV: 8 critical technology disruptions shape our unconstrained scenario and have implications on a sectoral energy use and the split between electrification, electron based molecules and carbon based fuels as solutions.
3. Hypotheses on sectoral help shape an unconstrained scenario, split between
 - i. No doubt electrification sectors (e.g. road, secondary steel)
 - ii. Fading barriers sectors (e.g. buildings and long-haul trucking)
 - iii. Potential breakthrough sectors (e.g. steel and cement)
